Alexander Abuabara

Causal Models

Causal revolution

Indicators

Causal models

Paths, doors, and adjustments

Decision models

Indicators

Godwin's Law

Godwin's law

From Wikipedia, the free encyclopedia

Godwin's law (or **Godwin's rule of Hitler analogies**)^{[1][2]} is an Internet **adage** asserting that "as an online discussion grows longer, the probability of a **comparison involving Nazis or Hitler approaches 1**".^{[2][3]} That is, if an online discussion (regardless of topic or scope) goes on long enough, sooner or later someone will compare someone or something to **Adolf Hitler** or his deeds, the point at which effectively the discussion or thread often ends.

Promulgated by the American attorney and author **Mike Godwin** in 1990,^[2] Godwin's law originally

Godwin's Law for statistics

SCIENCE

The Internet Blowhard's Favorite Phrase

Why do people love to say that correlation does not imply causation?

By DANIEL ENGBER

OCT 02, 2012 • 8:33 AM

Not everyone found the news believable. “Facepalm. Correlation doesn't imply causation,” wrote one unhappy Internet user. “That’s pretty much how I read this too... correlation is NOT causation,” agreed a Huffington Post superuser, seemingly distraught. “I was surprised not to find a discussion of correlation vs. causation,” cried someone at Hacker News. “Correlation does not mean causation,” a reader moaned at Slashdot. “There are so many variables here that it isn’t funny.”

Correlation does not
imply causation

Except when it does

Even if it doesn't,
this phrase is useless
and kills discussion

Correlation vs. causation

**How do we figure
out correlation?**

**How do we figure
out causation?**

Correlation vs. causation

How do we figure out correlation?

Math and statistics

How do we figure out causation?

Philosophy.
No math.

Causal relationships?

Lighting fireworks causes noise

Rooster crows cause the sunrise

Getting an MPA increases your earnings

Colds go away a few days
after you take vitamin C

Causation

**Causation =
Correlation + time order + nonspuriousness**

nonspuriousness means that a relationship observed between two variables is not due to the influence of a third

How do you know if you have it right?

You need a philosophical model

That's what this class is for!

John B. Holbein @JohnHolbein1 · Apr 7

Causality isn't achieved; it's approached.

Essencial parts

**Inputs, activities,
and outputs**

**Generally directly
measurable**

**# of citations mailed,
% increase in grades, etc.**

Outcomes

Harder to measure directly

Loftier and more abstract

**Commitment to school,
reduced risk factors**

Indicators

Y

Outcome variable

Response variable

Dependent variable

**Thing you want to
explain or predict**

X

Explanatory variable

Predictor variable

Independent variable

**Thing you use to
explain or predict Y**

Y "listens to" X

"A variable X is a cause of a variable Y if Y in any way relies on X for its value. ... X is a cause of Y if Y listens to X and decides its value in response to what it hears"

(Pearl, Glymour, and Jewell 2016, 5–6)

Y doesn't necessarily listen only to X

**A light switch causes a light to go on,
but not if the bulb is burned out (no Y despite X),
or if the light was already on (Y without X)**

Two purposes of modeling

Prediction

Forecast the future

Focus is on Y

Netflix trying to
guess your next show

Predicting who will enroll in SNAP

Explanation

Explain effect of X on Y

Focus is on X

Netflix looking at the effect of the
time of day on show selection

Measuring the effect of
SNAP on poverty reduction

**How do you measure
abstract outcomes?**

Move up the ladder of abstraction.

Ladder of abstraction for witches

Top rung: Broad, conceptual, hard to measure directly.
Bottom rung: Specific, tangible, observable.

Ladder of abstraction for witches

Mammal

Enmagicked

Trolls, elves, gods/goddesses

Female

Arwen, Winky, Athena

Human

Young

Salem witch trials

Student

Hermione Granger,
Sabrina Spellman

Old

Elphaba, Halloween
decorations

Connection to theory

"*My Wife and My Mother-in-Law*" is a famous optical illusion that depicts both an old woman looking off to the left and a young woman facing away, looking over her right shoulder. (The old woman's nose is the young woman's chin.)
(Image credit: Public Domain)

Causal models

Types of data

Experimental

**You have control over
which units get treatment**

Observational

**You don't have control
over which units get
treatment**

**Which kind lets you
prove causation?**

Causation with observational data

Can you prove causation with observational data?

Why is it so controversial to use observational data?

Laura Hatfield
@laura_tastic

Wow: this comment from fresh page proofs.

Guess all of us researching causal inference in observational data need to find new jobs?

Seva
@SevaUT

normal person: this rain is making us wet

me, RCT genius: whoa there! First, take twenty walks and randomly apply the rain treatment

Laura Hatfield @laura_tastic · Jan 16

Wow: this comment from fresh page proofs.

Guess all of us researching causal inference in observational data need to find new jobs?

The causal revolution

Causal diagrams

Directed acyclic graphs (DAGs)

Directed: Each node has an arrow that points to another node

Acyclic: You can't cycle back to a node (and arrows only have one direction, causal effects cannot be bidirectional)

Graph: It's... um... a graph

Causal diagrams

Directed acyclic graphs (DAGs)

Graphical model of the process that generates the data

Maps your philosophical model

Fancy math ("*do*-calculus") tells you what to control for to isolate and identify causation

Causal diagrams

Directed acyclic graphs (DAGs)

Computer science: data structure

Markov models: visualization

Explicitly identify assumptions

Illustrate sources of bias

Reduce bias

Separate individual effects

Ascertain appropriate covariates for statistical analysis

Causal diagrams

Directed acyclic graphs (DAGs)

Causal graphs are
based on assumptions

But so are analytic
models

Acyclicalness

What if there's something that really is cyclical?

Wealth $\rightarrow$ Power $\rightarrow$ Wealth

This isn't acyclic!
Wealth $\leftrightarrow$ Power

Split the node into different time periods

Wealth _{$t-1$} $\rightarrow$ Power _{t} $\rightarrow$ Wealth _{t}

How to draw a DAG

What is the causal effect of an additional year of education on earnings?

Step 1: List variables

Step 2: Simplify

Step 3: Connect arrows

Step 4: Use logic and math to determine which nodes and arrows to measure

1. List variables

Education (treatment) → Earnings (outcome)

Location

Ability

Demographics

Socioeconomic status

Year of birth

Compulsory schooling laws

Job connections

2. Simplify

Education (treatment) → Earnings (outcome)

Location

Ability

Demographics

Socioeconomic status

Year of birth

Compulsory schooling laws

Job connections

Background

3. Draw arrows

Education causes earnings

3. Draw arrows

Background, year of birth, location, and school requirements all cause education

3. Draw arrows

Background, year of birth, and location all
cause earnings too

3. Draw arrows

Education causes
job connections too

3. Draw arrows

Location and background are probably related, but neither causes the other. Something unobservable (**U1**) does that.

**Paths, doors,
and adjustments**

Causal identification

All these nodes are related; there's correlation between them all

We care about $\text{Edu} \rightarrow \text{Earn}$, but what do we do about all the other nodes?

Causal identification

A causal effect is *identified* if the association between treatment and outcome is properly stripped and isolated

Paths and associations

**Arrows in a DAG
transmit associations**

**You can redirect and control those paths
by "adjusting" or "conditioning"**

Three types of associations

Confounding

Common cause

Causation

Mediation

Collision

Selection /
endogeneity

Confounding

X causes Y

**But Z causes
both X and Y**

**Z confounds the
 $X \rightarrow Y$ association**

Paths

Paths between
X and Y?

$X \rightarrow Y$

$X \leftarrow Z \rightarrow Y$

Z is a
backdoor

d-connection

X and *Y* are "*d*-connected"
because associations can pass
through *Z*

The relationship
between *X* and *Y* is
not identified /
isolated

Effect of money on elections

What are the paths between money and win margin?

Money → Margin

Money ← Quality → Margin

Quality is a *backdoor*

Closing doors

Close the backdoor
by adjusting for Z

Closing doors

**Close the backdoor
by adjusting for Z**

Find the part of campaign money that is explained by quality, remove it. This is the residual part of money.

Find the part of win margin that is explained by quality, remove it. This is the residual part of win margin.

Find the relationship between the residual part of money and residual part of win margin. **This is the causal effect.**

How to adjust

Include term in regression

$$\text{Win margin} = \beta_0 + \beta_1 \text{Campaign money} + \beta_2 \text{Candidate quality} + \varepsilon$$

Matching

Stratifying

Inverse probability weighting

d-separation

If we control for Z,
X and Y are now
"*d*-separated" and
the association is
isolated!

NYT Health
@NYTHealth

Want to live longer? Try going to the opera. Researchers in Britain have found that people who reported going to a museum or concert even once a year lived longer than those who didn't.

Another Benefit to Going to Museums? You May Live Longer

Researchers in Britain found that people who go to museums, the theater and the opera were less likely to die in the study period than those who didn't.

Closing backdoors

Block all backdoor paths to identify the main pathway you care about

All paths

Education → Earnings

Education → Job connections → Earnings

Education ← Background → Earnings

Education ← Location → Earnings

Education ← Background ← U1 → Location → Earnings

Education ← Year → Earnings

Education ← Location ← U1 → Background → Earnings

All paths

Adjust for Location,
Background and Year to isolate
the **Education** → **Earnings**
causal effect

How do you know if this is right?

You can test the implications of the model to see if they're right in your data

$$X \perp Y | Z$$

X is independent of Y, given Z

Causation

Should you
control for Z?

No!

Overcontrolling

Causation and overcontrolling

Should you control for job connections?

Colliders

X causes Z

Y causes Z

Should you
control for Z?

Programming and social skills

Do programming skills reduce social skills?

You go to a tech company and conduct a survey. You find a negative relationship! Is it real?

Programming and social skills

Do programming skills reduce social skills?

No! Hired by a tech company is a collider and we controlled for it.

This inadvertently connected the two.

**Colliders can create
fake causal effects**

**Colliders can hide real
causal effects**

Height is unrelated to basketball skill... among NBA players

Colliders and selection bias

Colliders and selection bias

Three types of associations

Confounding

Common cause

Causation

Mediation

Collision

Selection /
endogeneity

Three types of associations

Endogeneity refers to a situation in statistical modeling where an independent variable is correlated with the error term, meaning there's a missing common cause or a causal relationship between the independent and dependent variables that the model doesn't account for.

This correlation, or **endogeneity**, invalidates the model's causal claims and leads to biased and inconsistent estimates of the relationship between variables.

Common causes of **endogeneity** include omitted variable bias, measurement error, and simultaneity, where variables influence each other.
